## **Overview**

Introduction

Essential operations

Linear curve fitting

Regularization

# Introduction

# Motivating linear algebra

Même le feu est régi par les nombres.

Fourier<sup>1</sup> studied the transmission of heat using tools that would later be called an eigenvector-basis. Why would he say something like this?

<sup>&</sup>lt;sup>1</sup>Jean Baptiste Joseph Fourier (1768-1830)

#### **Matrices**

 $\mathbf{A} \in \mathbb{R}^{m,n}$  is a real-valued Matrix with m rows and n columns.

$$\mathbf{A} = \begin{pmatrix} a_{11} & a_{12} & \dots & a_{1n} \\ a_{21} & a_{22} & \dots & a_{2n} \\ \vdots & \vdots & & \vdots \\ a_{m1} & a_{m2} & \dots & a_{mn} \end{pmatrix}, a_{ij} \in \mathbb{R}.$$
 (1)

3

# **Essential operations**

#### **Addition**

To matrices  $\mathbf{A} \in \mathbf{R}^{m,n}$  and  $\mathbf{B} \in \mathbf{R}^{m,n}$  can be added by adding their elements.

$$\mathbf{A} + \mathbf{B} = \begin{pmatrix} a_{11} + b_{11} & a_{12} + b_{12} & \dots & a_{1n} + b_{1n} \\ a_{21} + b_{21} & a_{22} + b_{22} & \dots & a_{2n} + b_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ a_{m1} + b_{m1} & a_{m2} + b_{m2} & \dots & a_{mn} + b_{mn} \end{pmatrix}$$
(2)

4

## Multiplication

Multiply  $\mathbf{A} \in \mathbb{R}^{m,n}$  by  $\mathbf{B} \in \mathbb{R}^{n,p}$  produces  $\mathbf{C} \in \mathbb{R}^{m,p}$ ,

$$\mathbf{AB} = \mathbf{C}.\tag{3}$$

To compute C the elements in the rows of A are multiplied with the column elements of C and the products added,

$$c_{ik} = \sum_{j=1}^{m} a_{ij} \cdot b_{jk}. \tag{4}$$

# Linear Algebra for Machine Learning in Python —Essential operations

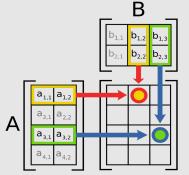

Multiply  $\mathbf{A} \in \mathbb{R}^{n,n}$  by  $\mathbf{B} \in \mathbb{R}^{n,p}$  produces  $\mathbf{C} \in \mathbb{R}^{n,p}$ .  $\mathbf{AB} = \mathbf{C}$ . (3) To compute  $\mathbf{C}$  the elements in the roots of  $\mathbf{A}$  are multiplied with the column elements of  $\mathbf{C}$  and the products added,  $\mathbf{Ca} = \sum_{j=1}^{n} a_{j} \cdot b_{j+1}$ . (4)

Multiplication

# -Multiplication

Define on the board:

- Dot product  $\mathbf{a} \cdot \mathbf{b} = a_1 b_1 + a_2 b_2 + \cdots + a_n b_n$  for two vectors  $\mathbf{a}, \mathbf{b} \in \mathbb{R}^n$ .
- Row times column view [Str+09]:

# The identity matrix

$$\mathbf{I} = \begin{pmatrix} 1 & & & \\ & 1 & & \\ & & \ddots & \\ & & & 1 \end{pmatrix} \tag{5}$$

└─The identity matrix

Demonstrate multiplication with the inverse by hand.

$$\begin{pmatrix} -1 & 0 & 0 \\ 1 & -1 & 1 \\ 1 & 0 & -1 \end{pmatrix} \begin{pmatrix} -1 & -0 & -0 \\ -2 & -1 & -1 \\ -1 & -0 & -1 \end{pmatrix} = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix} \tag{6}$$

 $I = \begin{pmatrix} 1 & & \\ & 1 & \\ & & \ddots & \\ & & & \ddots \end{pmatrix}$ (5)

## Matrix inverse

The inverse Matrix  $\mathbf{A}^{-1}$  undoes the effects of  $\mathbf{A}$ , or in mathematical notation,

$$\mathbf{A}\mathbf{A}^{-1} = \mathbf{I}.\tag{7}$$

The process of computing the inverse is called Gaussian elimination.

# Linear Algebra for Machine Learning in Python

Essential operations

└─Matrix inverse

Matrix inverse

The inverse Matrix  $A^{-1}$  undoes the effects of A, or in mathematical notation,  $AA^{-1} = I$ 

The process of computing the inverse is called Gaussian elimination.

## Example on the board:

$$\mathbf{A} = \begin{pmatrix} 2 & 0 \\ 1 & 3 \end{pmatrix} \rightsquigarrow \begin{pmatrix} 2 & 0 & 1 & 0 \\ 1 & 3 & 0 & 1 \end{pmatrix} \rightsquigarrow \begin{pmatrix} 1 & 0 & \frac{1}{2} & 0 \\ 1 & 3 & 0 & 1 \end{pmatrix} \tag{8}$$

$$\rightsquigarrow \begin{pmatrix} 1 & 0 & \frac{1}{2} & 0 \\ 0 & 3 & -\frac{1}{2} & 1 \end{pmatrix} \rightsquigarrow \begin{pmatrix} 1 & 0 & \frac{1}{2} & 0 \\ 0 & 1 & -\frac{1}{6} & \frac{1}{3} \end{pmatrix} \tag{9}$$

Test the result:

$$\begin{pmatrix} 2 & 0 \\ 1 & 3 \end{pmatrix} \begin{pmatrix} \frac{1}{2} & 0 \\ -\frac{1}{6} & \frac{1}{3} \end{pmatrix} = \begin{pmatrix} 2 \cdot \frac{1}{2} + 0 \cdot -\frac{1}{6} & 2 \cdot 0 + 0 \cdot \frac{1}{3} \\ 1 \cdot \frac{1}{2} + 3 \cdot -\frac{1}{6} & 0 \cdot 0 + 3 \cdot \frac{1}{3} \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}$$
(10)

# The Transpose

The transpose operation flips matrices along the diagonal, for example, in  $\mathbb{R}^2$ ,

$$\begin{pmatrix} a & b \\ c & d \end{pmatrix}^T = \begin{pmatrix} a & c \\ b & d \end{pmatrix}$$
 (11)

## Motivation of the determinant

- The determinant contains lots of information about a matrix in a single number.
- When a Matrix has a zero determinant, its inverse does not exist.
- We require determinants to find eigenvalues by hand.

# Computing determinants in two or three dimensions

The two-dimensional case:

$$\begin{vmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{vmatrix} = a_{11} \cdot a_{22} - a_{12} \cdot a_{21}$$
 (12)

(13)

Computing the determinant of a three-dimensional matrix.

$$\begin{vmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{vmatrix} = a_{11} \cdot \begin{vmatrix} a_{22} & a_{23} \\ a_{32} & a_{33} \end{vmatrix} - a_{21} \cdot \begin{vmatrix} a_{12} & a_{13} \\ a_{32} & a_{33} \end{vmatrix} + a_{31} \cdot \begin{vmatrix} a_{12} & a_{13} \\ a_{22} & a_{23} \end{vmatrix}$$

$$(14)$$

Example computation on the board:

dimensions

$$\begin{vmatrix} -1 & 0 & 0 \\ 1 & -1 & 1 \\ 1 & 0 & -1 \end{vmatrix} = -1 \cdot \begin{vmatrix} -1 & 1 \\ 0 & -1 \end{vmatrix} - 1 \cdot \begin{vmatrix} 0 & 0 \\ 0 & -1 \end{vmatrix} + 1 \cdot \begin{vmatrix} 0 & 0 \\ -1 & 1 \end{vmatrix}$$
 (15)
$$= (-1) \cdot ((-1) \cdot (-1) - 0 \cdot 1)) -$$
 (16)
$$(0 \cdot (-1) - 0 \cdot 0) + 0 \cdot 1 - (-1) \cdot 0$$
 (17)
$$= -1$$
 (18)

## **Determinants in n-dimensions**

$$\begin{vmatrix} a_{11} & a_{21} & \dots & a_{1n} \\ a_{21} & a_{22} & \dots & a_{2n} \\ \vdots & \vdots & & \vdots \\ a_{m1} & a_{m2} & \dots & a_{mn} \end{vmatrix} = a_{11} \begin{vmatrix} a_{22} & \dots & a_{2n} \\ \vdots & & \vdots \\ a_{m2} & \dots & a_{mn} \end{vmatrix} + a_{21} \begin{vmatrix} a_{21} & \dots & a_{2n} \\ \vdots & & \vdots \\ a_{m2} & \dots & a_{mn} \end{vmatrix}$$

 $ldsymbol{ldsymbol{ldsymbol{ldsymbol{ldsymbol{eta}}}}$  Determinants in n-dimensions

Draw the sign pattern on the board:

$$\begin{vmatrix} + & - & + & \dots \\ - & + & - & \dots \\ + & - & + & \dots \\ \vdots & \vdots & \vdots & \ddots \end{vmatrix}$$
 (19)

The determinant can be expanded along any column as long as the sign pattern is respected.

# **Summary**

- We saw some of the most important operations in linear algebra.
- Let's use these to do something useful next.

# **Linear curve fitting**

# What is the best line connecting measurements?

## **Problem Formulation**

A line has the form f(a) = da + c, with  $c, a, d \in \mathbb{R}$ . In matrix language, we could ask for every point to be on the line,

$$\begin{pmatrix} 1 & a_1 \\ 1 & a_2 \\ 1 & a_3 \\ \vdots & \vdots \\ 1 & a_n \end{pmatrix} \begin{pmatrix} c \\ d \end{pmatrix} = \begin{pmatrix} p_1 \\ p_2 \\ \vdots \\ p_n \end{pmatrix}. \tag{20}$$

We can treat polynomials as vectors, too! The coordinates populate the matrix rows in  $\mathbf{A} \in \mathbb{R}^{n_p \times 2}$ , and the coefficients appear in  $\mathbf{x} \in \mathbb{R}^2$ , with the points we would like to model in  $\mathbf{b} \in \mathbb{R}^{n_p}$ . The problem now appears in matrix form and can be solved using linear algebra!

# The Pseudoinverse [Str+09; DFO20]

The inverse exists for square or n by n matrices. Nonsquare  $\mathbf{A}$  such as the one we just saw, require the pseudoinverse,

$$\mathbf{A}^{\dagger} = (\mathbf{A}^{T} \mathbf{A})^{-1} \mathbf{A}^{T}. \tag{21}$$

Sometimes solving  $\mathbf{A}\mathbf{x} + \mathbf{b} = 0$  is impossible, the pseudoinverse considers,

$$\min_{\mathbf{x}} \frac{1}{2} |\mathbf{A}\mathbf{x} - \mathbf{b}|^2 \tag{22}$$

(23)

instead.  $\mathbf{A}^{\dagger}\mathbf{b} = \mathbf{x}$  yields the solution.

| Linear Algebra for Machine Learning in Python |  |
|---|--|
| 1 ,   | The inverse exists for square or n by n matrices. Nonsquare A such<br>as the one we just saw, require the pseudoinverse, |
| Linear curve fitting                          | $A^{\dagger} = (A^{T}A)^{-1}A^{T}$ . (21)  |
|   | Sometimes solving $\mathbf{A}\mathbf{x} + \mathbf{b} = 0$ is impossible, the pseudoinverse considers,                    |
| The Pseudoinverse [Str+09; DFO20]             | $\min_{x} \frac{1}{2}  \mathbf{A}\mathbf{x} - \mathbf{b} ^2 \qquad (22)$   |
| 1 110 1 30000 1100130 [501 7 03, 51 020]      | instead. All $\mathbf{b} = \mathbf{x}$ yields the solution.  |

 $\min_{\mathbf{v}} \frac{1}{2} |\mathbf{A}\mathbf{x} - \mathbf{b}|^2$ 

At the optimum we expect,

$$0 = \nabla_{\mathbf{x}} \frac{1}{2} |\mathbf{A}\mathbf{x} - \mathbf{b}|^{2}$$
$$= \nabla_{\mathbf{x}} \frac{1}{2} (\mathbf{A}\mathbf{x} - \mathbf{b})^{T} (\mathbf{A}\mathbf{x} - \mathbf{b})$$

Sometimes solving  $\mathbf{A}\mathbf{x} + \mathbf{b} = 0$  is implossible. One the board, derive:

$$(a - b)'$$

 $(\mathbf{A}^T\mathbf{A})^{-1}\mathbf{A}^T\mathbf{b} = \mathbf{x}$ 

$$= \mathbf{A}^T \mathbf{A} \mathbf{x}$$

$$= \mathbf{A}^T \mathbf{A} \mathbf{x} - \mathbf{A}^T \mathbf{b}$$

(24)

$$=
abla_{\mathbf{a}}^{1}|\mathbf{A}\mathbf{x}-\mathbf{b}|^{2}$$

$$0 = \nabla_x \frac{1}{2} |\textbf{A}\textbf{x} - \textbf{b}|^2$$

$$=\mathbf{A}^T(\mathbf{A}\mathbf{x}-\mathbf{b})$$

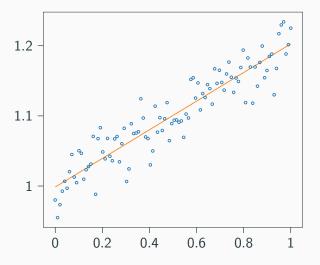

(30)

(31)

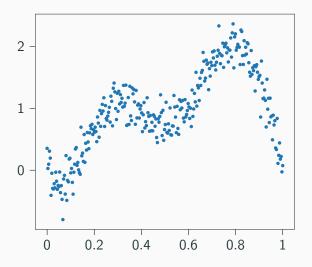

$$= \mathbf{A}^T \mathbf{A} \mathbf{x} - \mathbf{A}^T \mathbf{b}$$

$$\mathbf{A}^T\mathbf{b} = \mathbf{A}^T\mathbf{A}\mathbf{x}$$

# **Linear regression**

# What about harder problems?

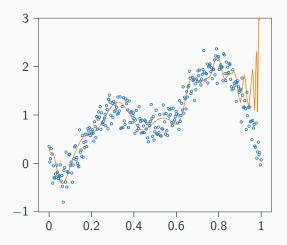

# Fitting higher order polynomials

$$\underbrace{\begin{pmatrix}
1 & a_1^1 & a_1^2 & \dots & a_1^m \\
1 & a_2^1 & a_2^2 & \dots & a_2^m \\
1 & a_3^1 & a_3^2 & \dots & a_3^m \\
\vdots & \vdots & \vdots & \ddots & \vdots \\
1 & a_n^1 & a_n^2 & \dots & a_n^m
\end{pmatrix}}_{\mathbf{A}}
\underbrace{\begin{pmatrix}
c_1 \\ c_2 \\ \vdots \\ c_m
\end{pmatrix}}_{\mathbf{x}} = \underbrace{\begin{pmatrix}
p_1 \\ p_2 \\ \vdots \\ p_n
\end{pmatrix}}_{\mathbf{b}}.$$
(32)

As we saw for the linear regression  $\mathbf{A}^{\dagger}\mathbf{b} = \mathbf{x}$  gives us the coefficients.

## Overfitting

The figure below depicts the solution for a polynomial of 7th degree, that is m = 7.

## **Summary**

- We saw how linear algebra lets us fit polynomials to curves.
- For the 7th-degree polynomial the noise took over! What now?

# Regularization

## Motivation

- Is there a way to fix the previous example?
- To do so we start from a rather peculiar observation.

# **Eigenvalues and Eigen-Vectors**

Multiply matrix **A** with vectors  $\mathbf{x_1}$  and  $\mathbf{x_2}$ ,

$$\mathbf{A} = \begin{pmatrix} 1 & 4 \\ 0 & 2 \end{pmatrix}, \mathbf{x}_1 = \begin{pmatrix} 1 \\ 0 \end{pmatrix}, \mathbf{x}_2 = \begin{pmatrix} 4 \\ 1 \end{pmatrix}, \tag{33}$$

we observe

$$\mathbf{A}\mathbf{x}_1 = \begin{pmatrix} 1 \\ 0 \end{pmatrix}, \mathbf{A}\mathbf{x}_2 = \begin{pmatrix} 8 \\ 2 \end{pmatrix} \tag{34}$$

Vector  $\mathbf{x_1}$  has not changed! Vector  $\mathbf{x_2}$  was multiplied by two. In other words,

$$Ax_1 = 1x_1, Ax_2 = 2x_2$$
 (35)

# **Eigenvalues and Eigenvectors**

Eigenvectors turn multiplication with a matrix into multiplication with a number,

$$\mathbf{A}\mathbf{x} = \lambda \mathbf{x}.\tag{36}$$

Subtracting  $\lambda x$  leads to,

$$(\mathbf{A} - \lambda \mathbf{I})\mathbf{x} = 0 \tag{37}$$

The interesting solutions are those were  $\mathbf{x} \neq \mathbf{0}$ , which means

$$\det(\mathbf{A} - \lambda \mathbf{I}) = 0 \tag{38}$$

# Linear Algebra for Machine Learning in Python —Regularization

Eigenvectors turn multiplication with a matrix into multiplication with a matrix into multiplication with a number.  $A_x = \lambda x. \tag{10}$  Subtracting  $\lambda x$  leads its,  $(A - \lambda t) x = 0 \tag{27}$  The interesting solutions are those were  $x \neq 0$ , which means  $\det (A - \lambda t) = 0 \tag{31}$ 

—Eigenvalues and Eigenvectors

On the board, compute the eigenvalues and vectors for the initial example.

$$\mathbf{A} = \begin{pmatrix} 1 & 4 \\ 0 & 2 \end{pmatrix} \rightarrow \begin{vmatrix} 1 - \lambda & 4 \\ 0 & 2 - \lambda \end{vmatrix} = (1 - \lambda) * (2 - \lambda) - 0 * 4 = 0 \quad (39)$$

$$\rightarrow \lambda_1 = 1, \lambda_2 = 2. \quad (40)$$

$$\begin{pmatrix} 1 - 1 & 4 \\ 0 & 2 - 1 \end{pmatrix} = \begin{pmatrix} 0 & 4 \\ 0 & 1 \end{pmatrix} \mathbf{x}_1 = 0 \rightarrow \mathbf{x}_1 = \begin{pmatrix} p \\ 0 \end{pmatrix} \text{ for } p \in \mathbb{R} \quad (41)$$

$$\begin{pmatrix} 1 - 2 & 4 \\ 0 & 2 - 2 \end{pmatrix} = \begin{pmatrix} -1 & 4 \\ 0 & 0 \end{pmatrix} \mathbf{x}_1 = 0 \rightarrow \mathbf{x}_2 = \begin{pmatrix} q \\ \frac{1}{4}q \end{pmatrix} \text{ for } q \in \mathbb{R} \quad (42)$$

Determinant not useful numerically, software packages use QR-Method.

# Eigenvalue-Decomposition [Str+09]

Eigenvalues let us look into the heart of a square system-matrix  $\mathbf{A} \in \mathbb{R}^{n,n}$ .

$$\mathbf{A} = \mathbf{S} \begin{pmatrix} \lambda_1 & & & \\ & \lambda_2 & & \\ & & \ddots & \\ & & & \lambda_n \end{pmatrix} \mathbf{S}^{-1} = \mathbf{S} \wedge \mathbf{S}^{-1}, \tag{43}$$

with  $\mathbf{S} \in \mathbb{R}^{n,n}$  and  $\Lambda \in \mathbb{C}^{n,n}$ .

# Singular-Value-Decomposition [Str+09]

What about a non-square matrix  $\mathbf{A} \in \mathbb{R}^{n,m}$ ? Idea:

$$\mathbf{A}^{\mathsf{T}}\mathbf{A} = \mathbf{V} \begin{pmatrix} \sigma_1^2 & & \\ & \ddots & \\ & & \sigma_n^2 \end{pmatrix} \mathbf{V}^{-1}, \mathbf{A}\mathbf{A}^{\mathsf{T}} = \mathbf{U} \begin{pmatrix} \sigma_1^2 & & \\ & \ddots & \\ & & \sigma_n^2 \end{pmatrix} \mathbf{U}^{-1}.$$

$$\tag{44}$$

Using the eigenvectors of the  $\mathbf{A}^T\mathbf{A}$  and  $\mathbf{A}\mathbf{A}^T$  we construct,

$$\mathbf{A} = \mathbf{U} \mathbf{\Sigma} \mathbf{V}^T, \tag{45}$$

with  $\mathbf{A} \in \mathbb{R}^{m,n}$ ,  $\mathbf{U} \in \mathbb{R}^{m,m}$ ,  $\Sigma \in \mathbb{R}^{m,n}$  and  $\mathbf{V} \in \mathbb{R}^{n,n}$ .

# Singular values and matrix inversion [GK65]

$$\mathbf{A}^{\dagger} = \mathbf{V} \mathbf{\Sigma}^{\dagger} \mathbf{U}^{T} = \mathbf{V} \begin{pmatrix} \sigma_{1}^{-1} & & \\ & \ddots & \\ & & \sigma_{m}^{-1} \end{pmatrix} \mathbf{U}^{T}$$
 (46)

# Regularization via Singular Value Filtering

Originally we had a problem computing  $\mathbf{A}^{\dagger}\mathbf{b}=\mathbf{x}.$  To solve it, we compute,

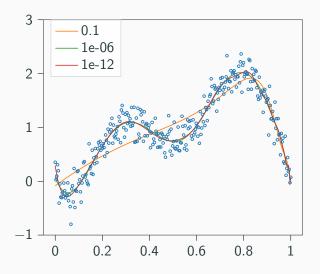

$$\mathbf{x}_{reg} = \sum_{i=1}^{n} f_i \frac{\mathbf{u}_i^T b}{\sigma_i} \mathbf{v_i}$$
 (47)

The filter factors are computed using  $f_i = \sigma_i^2/(\sigma_i^2 + \epsilon)$ . Singular values  $\sigma_i < \epsilon$  are filtered. Expressing equation 47 using matrix notation:

$$\mathbf{x}_{reg} = \mathbf{VF} \begin{pmatrix} \sigma_1^{-1} & & & \\ & \ddots & & \\ & & \sigma_m^{-1} & \\ & & 0 \end{pmatrix} \mathbf{U}^T \mathbf{b}_{noise}$$
 (48)

with  $\mathbf{A} \in \mathbb{R}^{m,n}$ ,  $\mathbf{U} \in \mathbb{R}^{m,m}$ ,  $\mathbf{V} \in \mathbb{R}^{n,n}$ ,  $\mathbf{F} \in \mathbb{R}^{m,m}$ ,  $\Sigma^{\dagger} \in \mathbb{R}^{n,m}$  and  $\mathbf{b} \in \mathbb{R}^{n,1}$ .

# Regularized solution

#### **Conclusion**

- True scientists know what linear can do for them!
- Think about matrix shapes. If you are solving a problem, rule out all formulations where the shapes don't work.
- Regularization using the SVD is also known as Tikhonov regularization.
